

# MOM PS Estimator under Strong Monotonicity

January 11, 2021

Say members of the control group of an RCT have no access to the treatment, but among the treatment group there are compliers and non-compliers—i.e. one-sided non-compliance. (Of course, this could be, e.g., compliance in two different ways, etc.) Then there are two principal strata  $S$ , never-takers and compliers. Say the exclusion restriction doesn't hold.

Feller et al. [2017] and Ding and Lu [2017] and others discuss estimating principal effects in one-sided noncompliance (which they call “strong monotonicity”) under the assumption of principal ignorability, viz.  $Y_C \perp\!\!\!\perp S|\mathbf{X}$ . This has two problems, to my mind:

1. Sometimes principal ignorability is not plausible
2. If you assume the principal ignorability for  $Y_T$  (“strong” principal ignorability) then, as Feller et al. [2017] points out, the principal effects conditional on covariates are equal to the ITT conditional on covariates—the stratum plays no role. But sometimes the role of the strata is what we're trying to estimate!

The approach here takes a different tack, based on a different assumption which is maybe even less plausible—but which, I think, can be relaxed.

## 1 Setup

Estimating  $\mathbb{E}[Y_T|S]$  is straightforward, so for the remainder just consider the “control” group,  $Z = 0$ , with  $n$  (control) subjects and drop the  $C$  subscript. The control group is a mixture of compliers and never-takers.

For subject  $i$ ,  $i = 1, \dots, n$ , we have:

- $Y_i$  observed outcome
- $S_i \in \{0, 1\}$  unobserved stratum

- $e(\mathbf{X}_i) = Pr(S_i = 1|\mathbf{X}_i)$  take as given (like, estimated from treatment group)

Let  $\mu_0 = \mathbb{E}[Y|S = 0]$  and  $\mu_1 = \mathbb{E}[Y|S = 1]$ . The goal is to estimate  $\mu_0$  and  $\mu_1$ .

**Assumption:**

$$\mathbb{E}[Y_i|\mathbf{X}_i, S_i] = \mathbb{E}[Y_i|S_i] = \mu_0 \text{ or } \mu_1 \quad (1)$$

i.e.  $Y$  is mean-independent of  $\mathbf{X}$  conditional on  $S$ . This is problematic—why should  $S$  contain all information about  $Y$ ?

Note, it is kinda related to “principal ignorability“ of Feller et al. [2017] and Ding and Lu [2017],  $Y \perp\!\!\!\perp S|\mathbf{X}_i$  but, obviously, different too.

## 2 MOM Estimator

First, relating  $\bar{Y}$  to  $\mu_0$  and  $\mu_1$ .

$$\mathbb{E}[Y_i|\mathbf{X}_i] = \mathbb{E}\{\mathbb{E}[Y_i|\mathbf{X}_i, S_i]\} = \mu_1 e(\mathbf{X}_i) + \mu_0(1 - e(\mathbf{X}_i))$$

Hence the first estimating equation is

$$\bar{Y} = \hat{\mu}_1 \overline{e(\mathbf{X})} + \hat{\mu}_0(1 - \overline{e(\mathbf{X})}) \quad (2)$$

Second,

$$\begin{aligned} \mathbb{E}[Y_i e(\mathbf{X}_i)] &= \mathbb{E}\mathbb{E}[Y_i e(\mathbf{X}_i)|e(\mathbf{X}_i)] \\ &= \mathbb{E}\{e(\mathbf{X}_i)\mathbb{E}\mathbb{E}[Y_i|e(\mathbf{X}_i), S_i]\} \\ &= \mathbb{E}\{e(\mathbf{X}_i)\mathbb{E}\mathbb{E}[Y_i|S_i]\} \text{ by (1)} \\ &= \mathbb{E}\{\mu_1 e(\mathbf{X}_i)^2 + \mu_0(1 - e(\mathbf{X}_i))e(\mathbf{X}_i)\} \end{aligned}$$

Then the 2nd estimating equation is

$$\overline{Y e(\mathbf{X})} = \hat{\mu}_1 \overline{e(\mathbf{X})^2} + \hat{\mu}_0(\overline{e(\mathbf{X})} - \overline{e(\mathbf{X})^2})$$

Solving gives the estimates:

$$\hat{\mu}_0 = \frac{\overline{e(\mathbf{X})} \overline{Y e(\mathbf{X})}}{(\bar{Y} - 1)\overline{e(\mathbf{X})^2} + \overline{e(\mathbf{X})}^2}$$

and

$$\hat{\mu}_1 = \frac{\bar{Y} - (1 - \overline{e(\mathbf{X})})\hat{\mu}_0}{\overline{e(\mathbf{X})}}$$

### 3 Relaxing (1) with regression

There's no particular reason to assume (1) and it seems like it would typically be pretty implausible.

But say you believe the model

$$Y_i = \mathbf{x}_i' \boldsymbol{\beta} + \gamma S_i + \epsilon_i \quad (3)$$

Then instead of (1) we could assume something like

$$\mathbb{E}[Y_i - \mathbf{x}_i' \boldsymbol{\beta} | \mathbf{X}_i, S_i] = \mathbb{E}[Y_i - \mathbf{x}_i' \boldsymbol{\beta} | S_i]$$

in other words, no interaction between  $\mathbf{X}$  and  $S$  in (1). Then, if you had an estimate for  $\boldsymbol{\beta}$ , you could just substitute  $Y_i - \mathbf{x}_i' \boldsymbol{\beta}$  for  $Y_i$  in the estimates. Alternatively, you could use a stacked estimating equation approach and estimate it all together.
